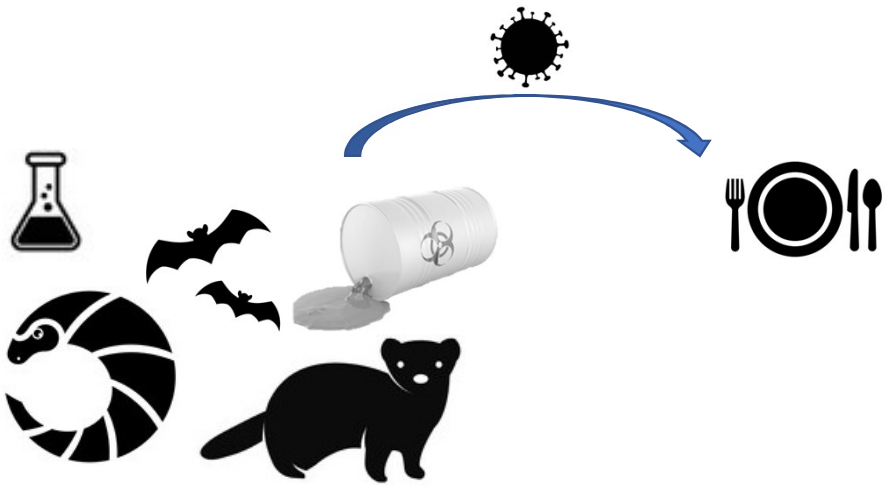
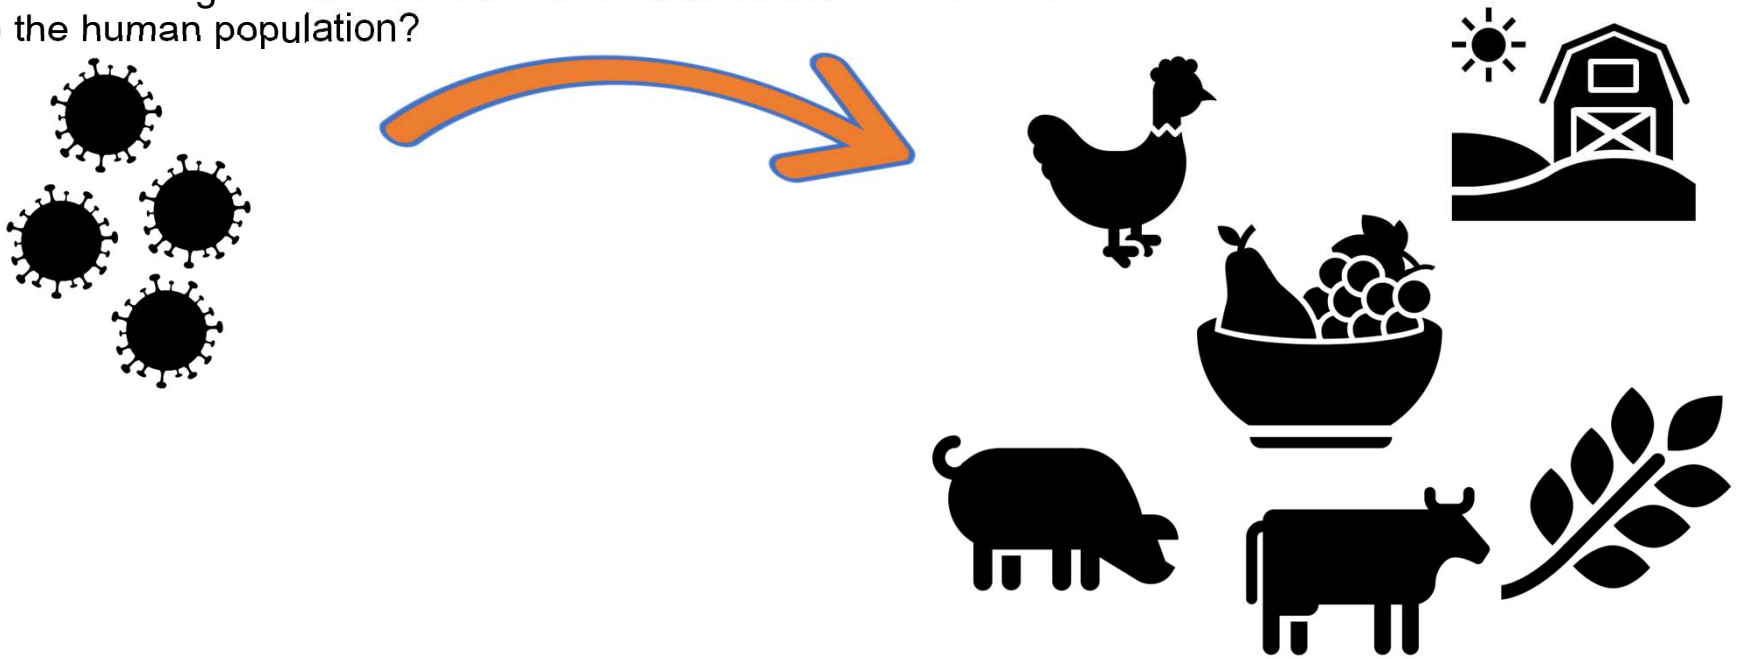
Possible source of virus SARS-CoV-2, animals may be natural hosts. Is it a zoonoses?



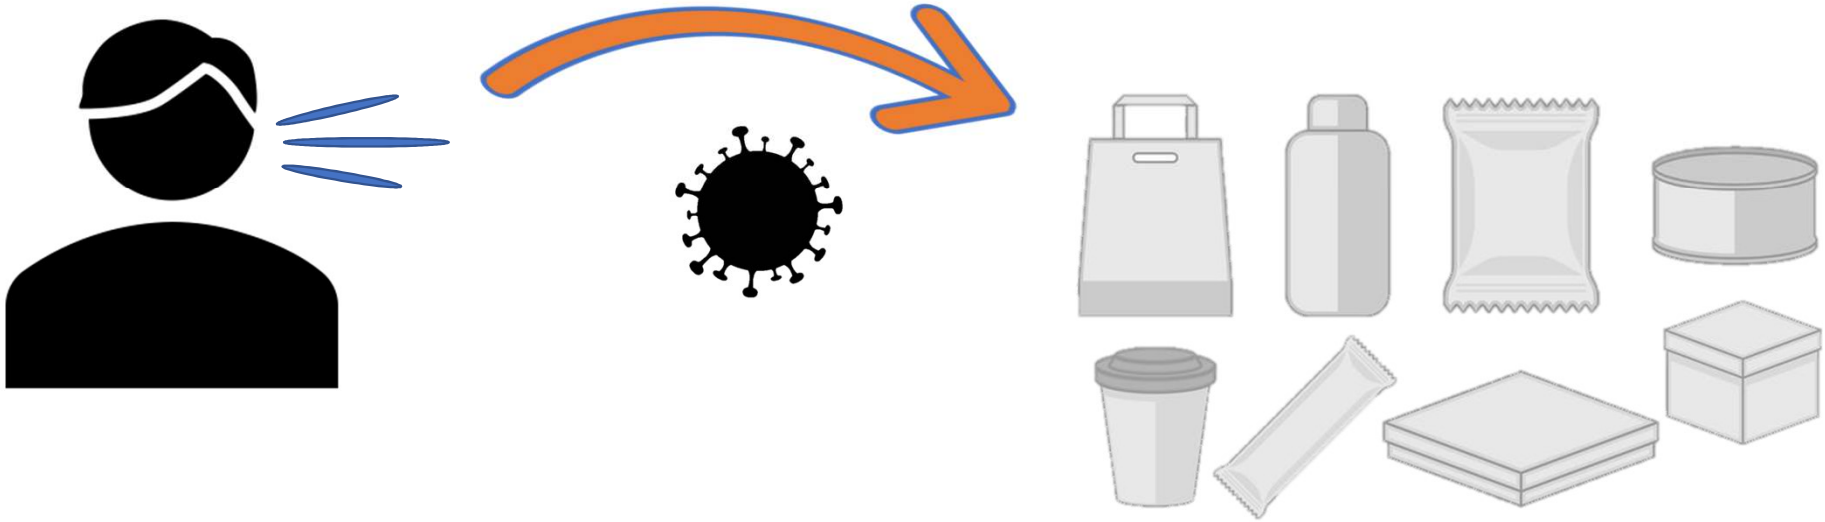
In particular, the role (if any) of **domesticated food-producing animals and the meat derived from them**

- necessitating the development of suitable diagnostic protocols; implementation of intervention measures along the food chain and recognising transmission routes.

- Could also be possible for SARS- CoV-2 a series of barrier jumps?
- Are food preparations and cooking habits considered a risk factors for the re-emergence of this virus in the human population?



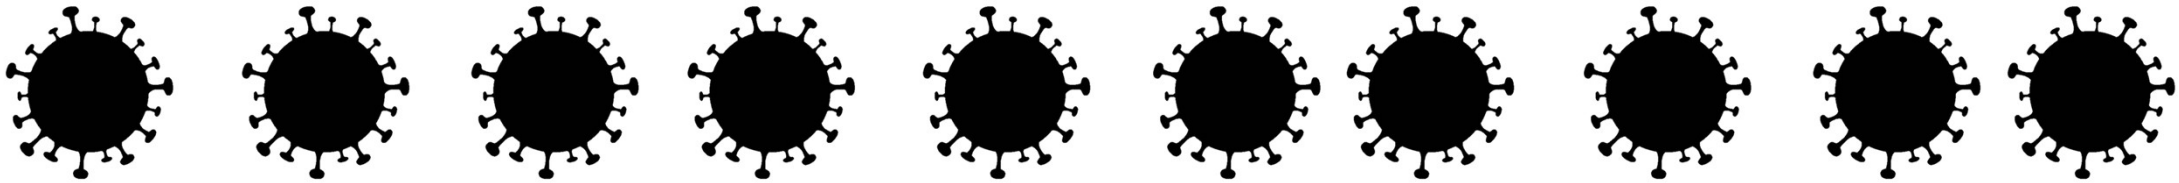
Of concern are **processed foods and food packaging**, wherein the SARS-CoV-2 could reach a susceptible consumer following cross-contamination from a previously infected individual (after bouts of coughing or sneezing).



Although there is no direct and credible evidence to state that COVID-19 is a food-borne disease, contact with food and food packaging surfaces remains a low risk in the context of the ongoing pandemic.

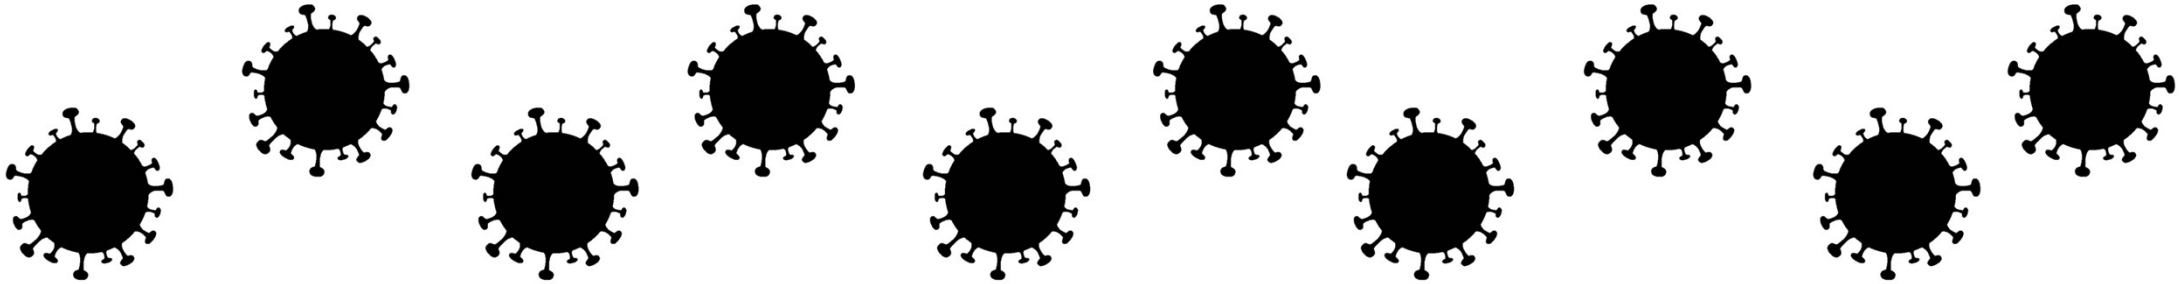
The **COVID-19 pandemic has presented several challenges to stakeholders along the food chain.** These must be overcome in order to ensure food safety and will involve the ability to reliably detect the virus in various food matrices and the built food production environment. As we move towards a post-pandemic era, public health surveillance will involve not only screening human populations, but also monitoring of foods; preparation surfaces and related environments, to assess risk and implement scientifically- based countermeasures.

Although, several **meat processing plants (MPPs)** in the US, Europe and elsewhere, suspended operations, when workers tested positive, though no food recalls were instituted

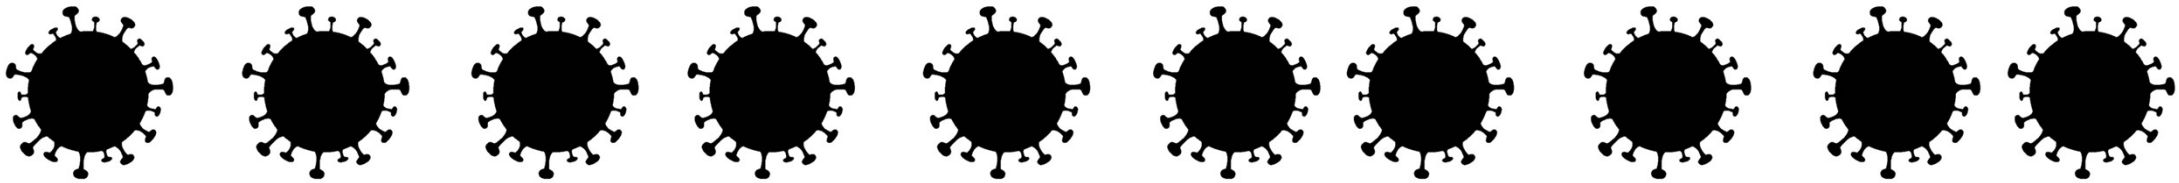


This project would set out to provide with evidence on the following:

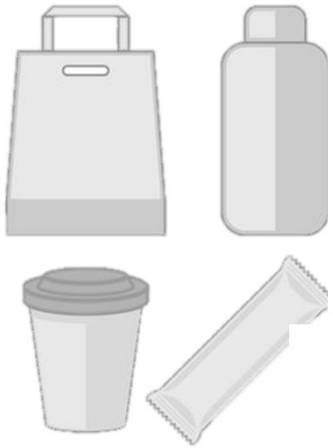
- describe the detection of SARS-CoV-2 in selected food matrices (raw meat; selected vegetables and fruits);
- describe the detection of SARS-CoV-2 in selected built food processing environments (FPP) to include sampling of various locations (including taps; door handles; refrigerator handles; smear samples from air conditioning units and other locations considered high-touch);
- determine the whole virus genome sequence (WvGS) of all viral strains recovered from selected food matrices and locations within the built food production environments;
- using WvGS make provide data describing a comparative genomic study to provide information on the potential relationships between these foods, ecological niches and those sequences deposited within GISAID

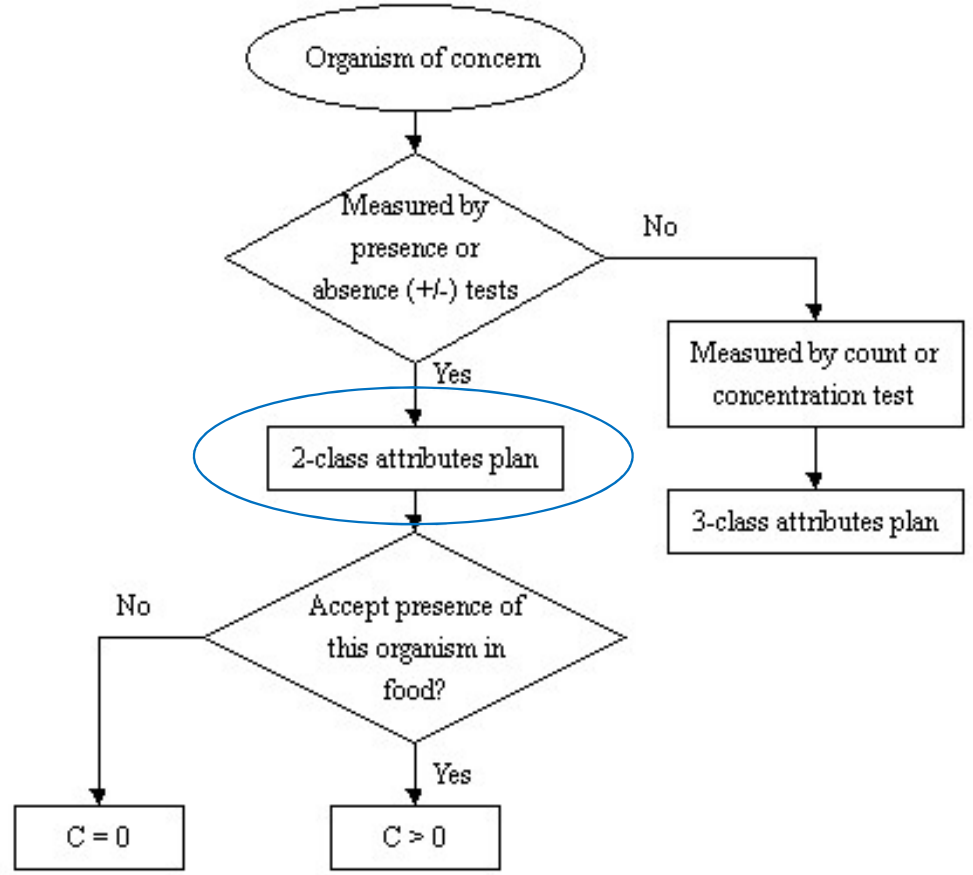


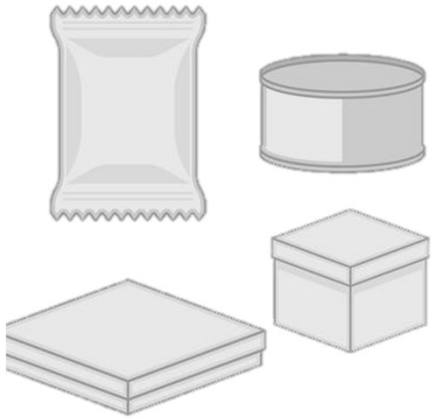
- Identification of SARS-CoV-2 RNA in selected food production environments and foods, by RT-qPCR
- Characterisation of qPCR positive samples by whole virus genome sequencing (WvGS) and comparative genome analysis of these viral strains with those globally available



Sampling plan: the model







Assuming that in this study is preferred a sampling plan with the highest confidence on the results, among the binomial staged sampling plans, is chosen the table with the confidence limit of **0.99 and 0.10** as the upper confidence level.

Sampling plan: the model

Confidence Limit .99		0 out of:	1 out of:	2 out of:
A	.30 ucl*	15	22	27
B	.25 ucl	19	27	34
C	.20 ucl	24	34	43
D	.15 ucl	35	47	59
E	.10 ucl	51	73	90
F	.05 ucl	107	161	190

Using this approach, for each type of food is ideally preferred a **number of 51 samples**.

1. **Food samples**
   - Raw meat
   - Vegetables
   - Fruit
2. **Abiotic surfaces of high-touch locations**
   - Air conditioning units;
   - Taps;
   - Door handles;
   - Refrigeration handles
   - Others
3. **Sewage from selected food/meat processing plants**

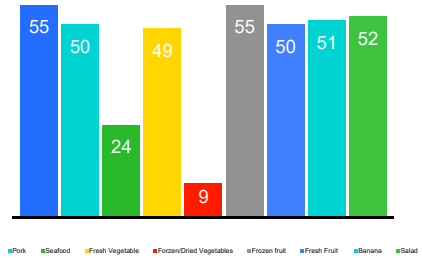
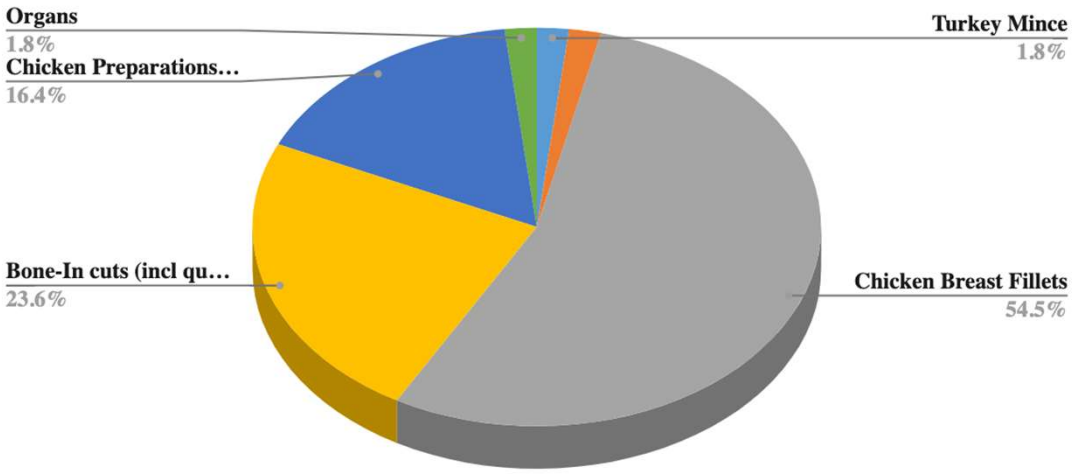
101 fresh vegetables RTE

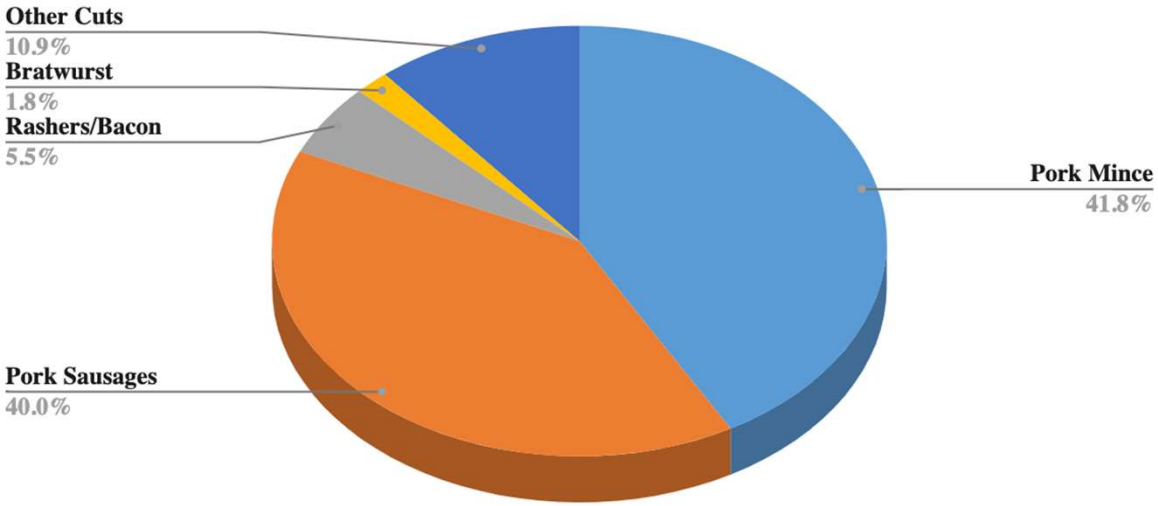
157 fruit RTE (fresh/frozen)



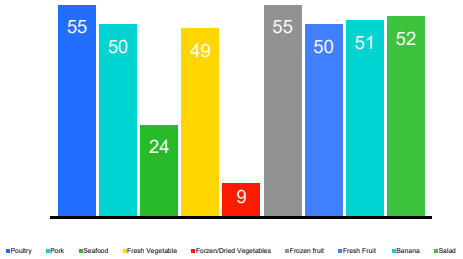
Poultry Sample Types - WHO Food SARS-COV-2

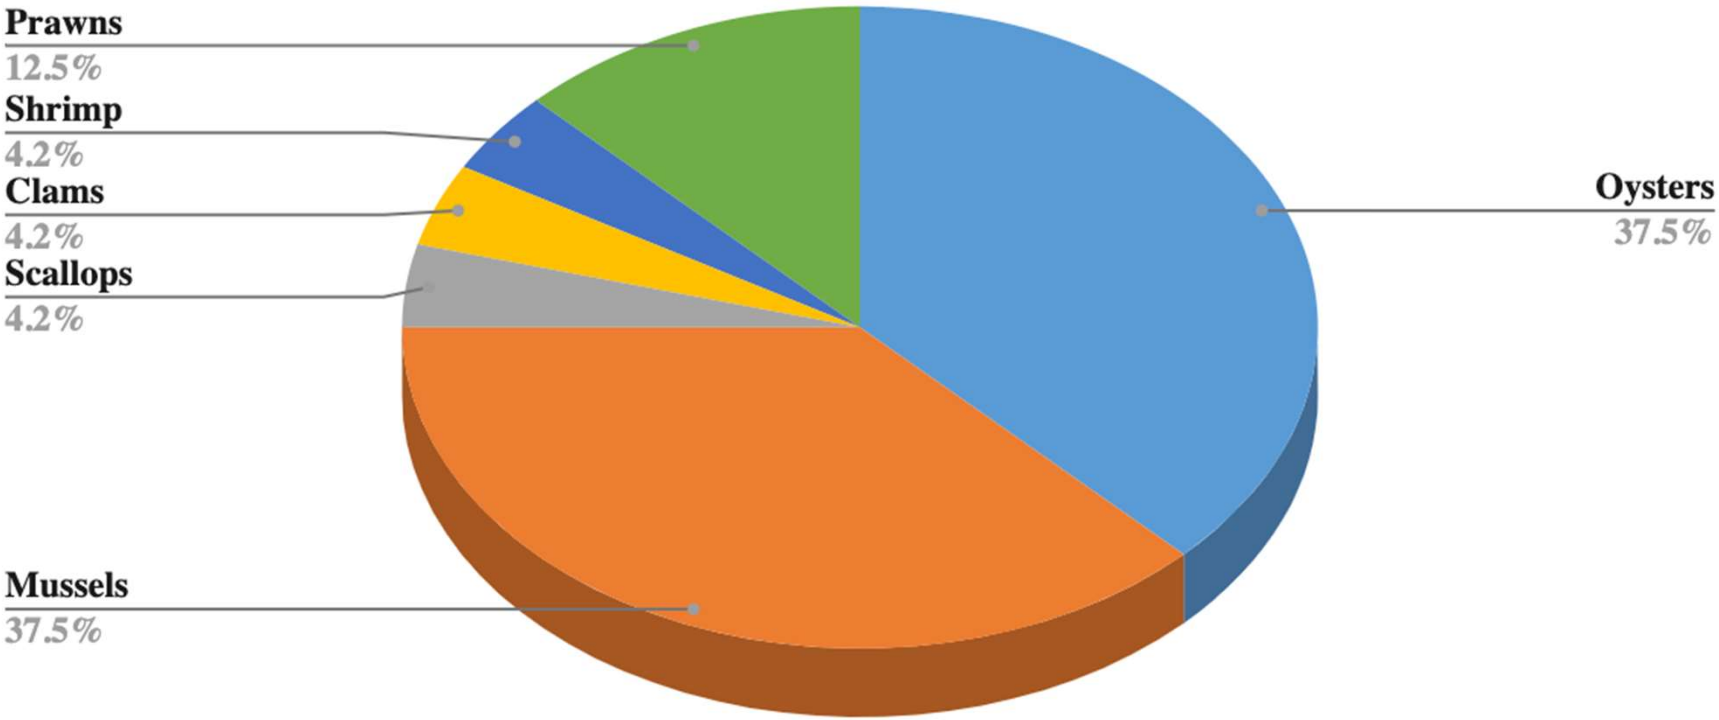


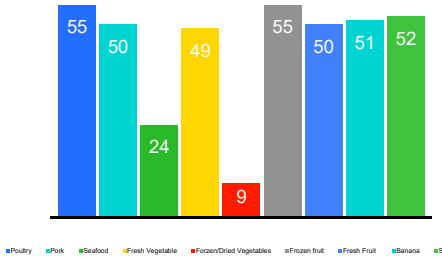
Pork Sample Types - WHO Food SARS-COV-2



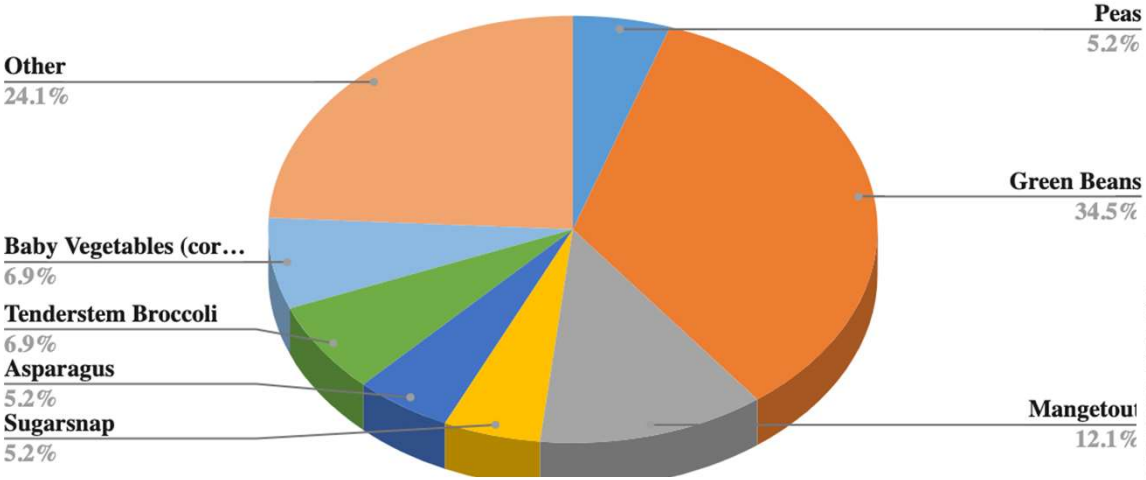
Seafood Sample Types - WHO Food SARS-COV-2



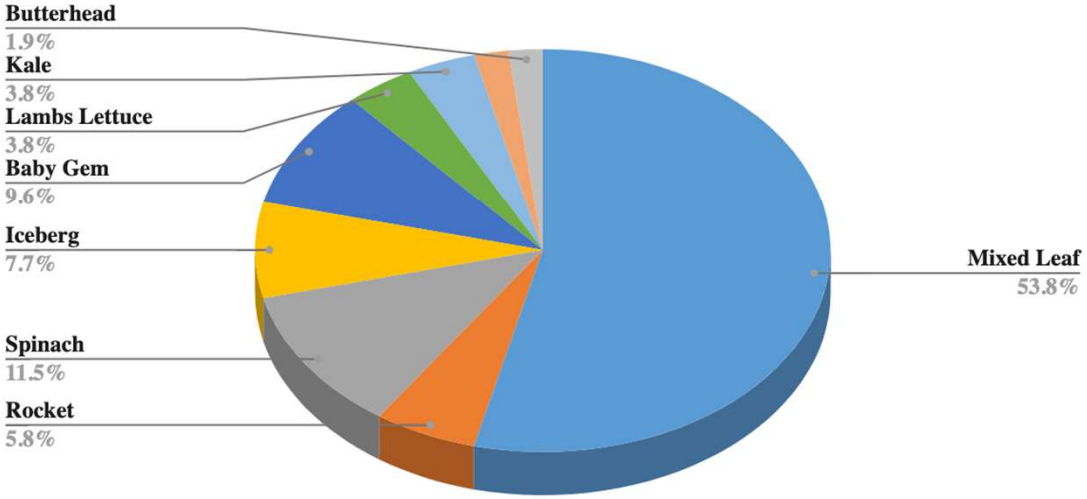




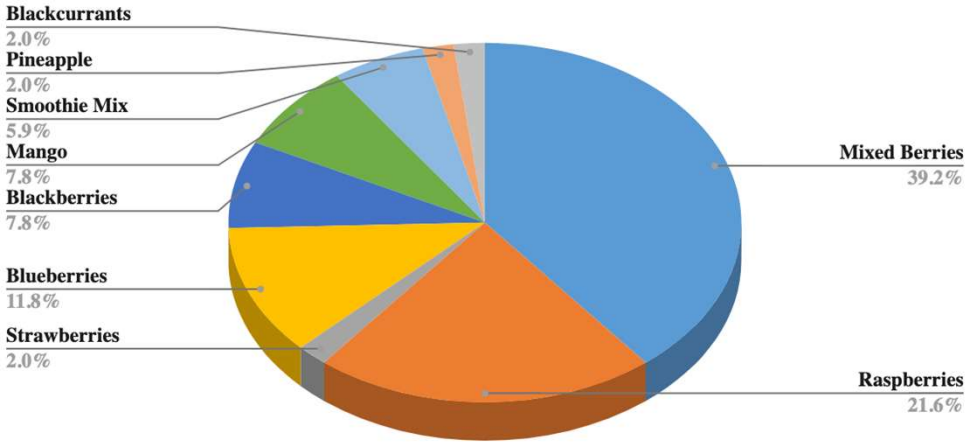
Vegetable Sample Types - WHO Food SARS-COV-2



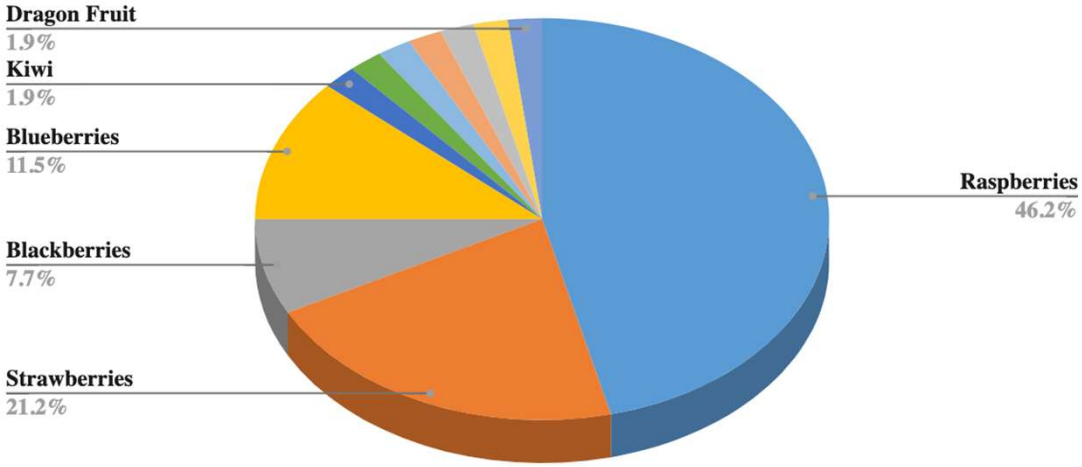
RTE Salad Sample Types - WHO Food SARS-COV-2



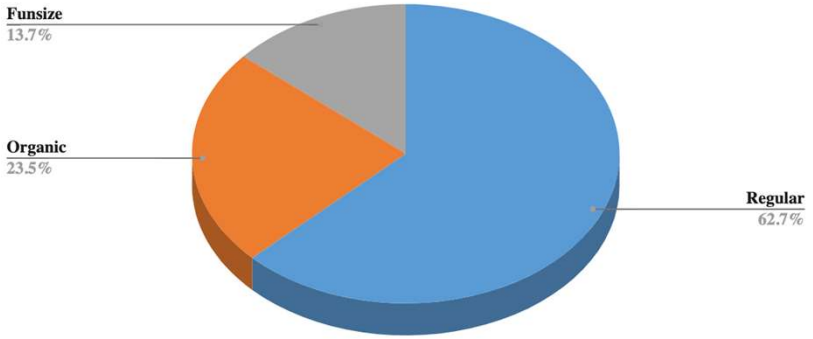
Frozen Fruit Sample Types - WHO Food SARS-COV-2

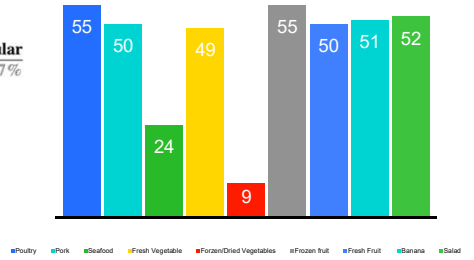


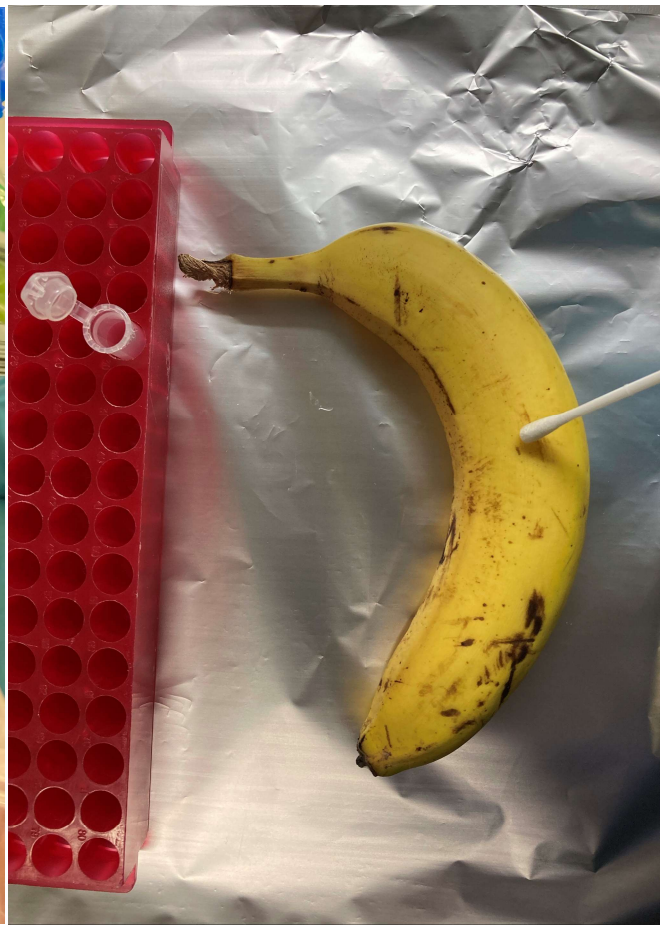
Fresh Fruit Sample Types - WHO Food SARS-COV-2



Banana Sample Types - WHO Food SARS-COV-2



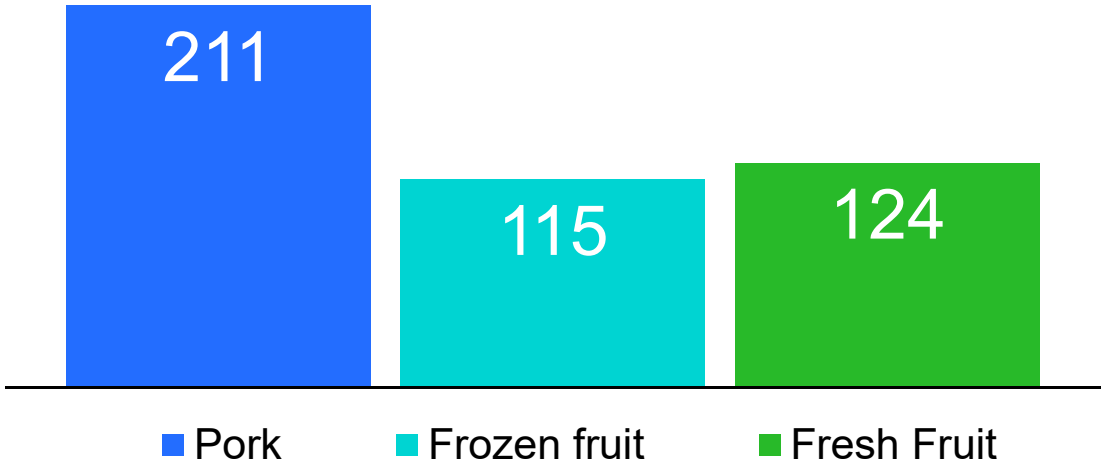




All the packaging were tested as surface swabs, including skin of bananas

367 samples

Retrospective study



Pork meat

- Small sausages: 74
- Large sausages: 63
- Fermented sausages: 45
- Pork liver: 29

Small Fruits

- Raspberry: 61
- Strawberry: 63
- Frozen Raspberry: 56
- Frozen Strawberry: 59

Abiotic surfaces of high-touch locations

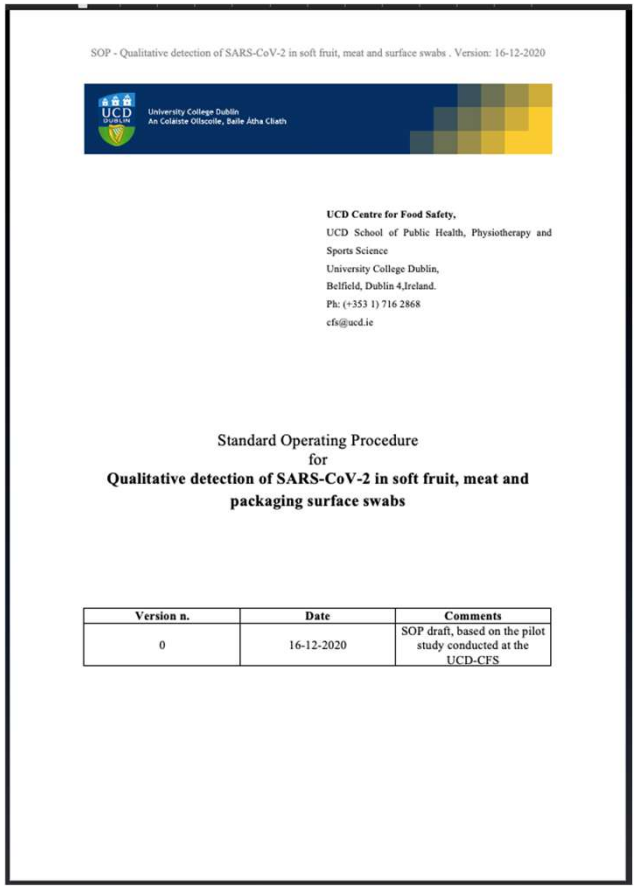
Wastewater samples

The samples were collected from a **line of untreated wastewater** (e.g., lift stations, interceptors, manholes) includes **waste from building use** (e.g., toilets, showers, sinks), which contains human faecal waste, as well as the waste of industrial use/rainwater.

Bangor University, 2020

Collection of the samples:

- **composite samples** are collected by **pooling multiple grab samples** at a specified frequency over a set time period – typically 8 hours for wastewater surveillance. You can collect composite samples of untreated wastewater manually (e.g., one sub-sample per 500 cubic meters of flow or 125 ml every 2 hours).
- **rapidly in one time (grab sample) reaching the point for the sampling**. However, grab samples may be less representative of community fecal contributions than composite samples. For untreated wastewater and sludge, grab samples represent a single moment in time and are highly influenced by daily fluctuations in wastewater flow and composition. If this is the case, we suggest taking the sample at the highest pick of usage in the working day.



SOP - Qualitative detection of SARS-CoV-2 in soft fruit, meat and surface swabs . Version: 16-12-2020

Standard Operating Procedure
for
Qualitative detection of SARS-CoV-2 in soft fruit, meat and packaging surface swabs

Version n.	Date	Comments
0	16-12-2020	SOP draft, based on the pilot study conducted at the UCD-CFS

- Remove the individually wrapped swab from the envelope and immerge immediately into sterile tubes containing 1-3 mL of VTM;
- Lightly tap the swab tip to the inside of the transport container to remove excess transport medium (liquid);
- Use swab to sample surface areas of interest (25 cm^2 is commonly used but a specified area is not required). Swab with moderate pressure while moving in at least two different directions and rotating the swab so that the entire swab surface area is used. Avoid letting the swab dry completely.
- Immediately after sampling, place the swab back into the transport container, cut the stick at the breakpoint, bending gently and screw the cap on tightly.

Date	Swab No.	Area	Location

Published online 24 May 2017; doi:10.1038/nprot.2017.066

Genome sequencing has become a powerful tool for studying emerging infectious diseases; however, genome sequencing directly from clinical samples (i.e., without isolation and culture) remains challenging for viruses such as Zika, for which metagenomic sequencing methods may generate insufficient numbers of viral reads. Here we present a protocol for generating coding-sequence-complete genomes, comprising an online primer design tool, a novel multiplex PCR enrichment protocol, optimized library preparation methods for the portable MinION sequencer (Oxford Nanopore Technologies) and the Illumina range of instruments, and a bioinformatics pipeline for generating consensus sequences. The MinION protocol does not require an Internet connection for analysis, making it suitable for field applications with limited connectivity. Our method relies on multiplex PCR for targeted enrichment of viral genomes from samples containing as few as 50 genome copies per reaction. Viral consensus sequences can be achieved in 1–2 d by starting with clinical samples and following a simple laboratory workflow. This method has been successfully used by several groups studying Zika virus evolution and is facilitating an understanding of the spread of the virus in the Americas. The protocol can be used to sequence other viral genomes using the online Primal Scheme primer designer software. It is suitable for sequencing either RNA or DNA viruses in the field during outbreaks or as an inexpensive, convenient method for use in the lab.

INTRODUCTION

Genome sequencing of viruses has been used to study the spread of disease in outbreaks[1]. Real-time genomic surveillance is important in managing viral outbreaks, as it can provide insights into how viruses transmit, spread and evolve[1–4]. Such work depends on rapid sequencing of viral material directly from clinical samples—i.e., without the need to isolate the virus in pure culture. During the Ebola virus epidemic of 2013–2016, prospective viral genome sequencing was able to provide critical information on virus evolution and help inform epidemiological investigations[3–6]. Sequencing directly from clinical samples is faster, less laborious and more amenable to near-patient work than time-consuming culture-based methods. Metagenomics, the process of sequencing the total nucleic acid content in a sample (typically cDNA or DNA), has been successfully applied to both virus discovery and diagnostics[7–9]. Metagenomic approaches have seen rapid adoption over the past decade, fueled by relentless improvements in the yield of high-throughput sequencing instruments[5,10–12]. Whole-genome sequencing of Ebola virus directly from clinical samples without amplification was possible because of the extremely high virus copy numbers found in acute cases[13–15]. However, direct metagenomic sequencing from clinical samples poses challenges with regard to sensitivity: genome coverage may be low or absent when attempting to sequence viruses that are present at low abundance in a sample with high levels of host nucleic acid background.

Development of the protocol

During recent work on the Zika virus epidemic[16], we found that it was difficult to generate whole-genome sequences directly from clinical samples using metagenomic approaches (**Table 1**). These samples had cycle threshold (Ct) values between 33.9 and 35.9 (equivalent to 10–48 genome copies per microliter). Before sequencing, these samples were depleted of human rRNA and prepared for metagenomic sequencing on the Illumina MiSeq platform as previously described[2,17]. In these cases, sequences from Zika virus comprised <0.01% of the data set, resulting in incomplete coverage. Greater coverage and depth are critical for accurate genome reconstruction and subsequent phylogenetic inference. In addition, there are substantial sequencing, analysis and storage costs associated with generating large sequencing data sets; therefore, metagenomic approaches currently do not lend themselves to the cost-effective use of lower-throughput portable sequencing devices such as the Oxford Nanopore MinION.

Sequencing

Implemented a protocol for extracting the viral particles from the spent rapid tests

Extraction of high quality viral RNA

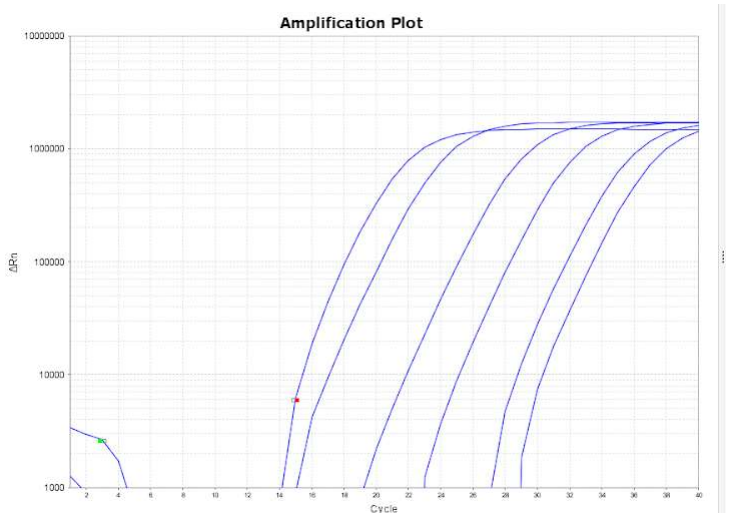
Direct Sequencing (not needed a second swabs from tested positive)

Detection of variants, tracing outbreaks, surveillance, *system for future outbreaks?*

Results – sampling and RT-qPCR

- 10 samples pooled
- Plasmidic DNA
- RNA positive samples
- Process control (MeV) lysis step.

1,261 samples in total



Results

The matrices were extracted and tested in ten units

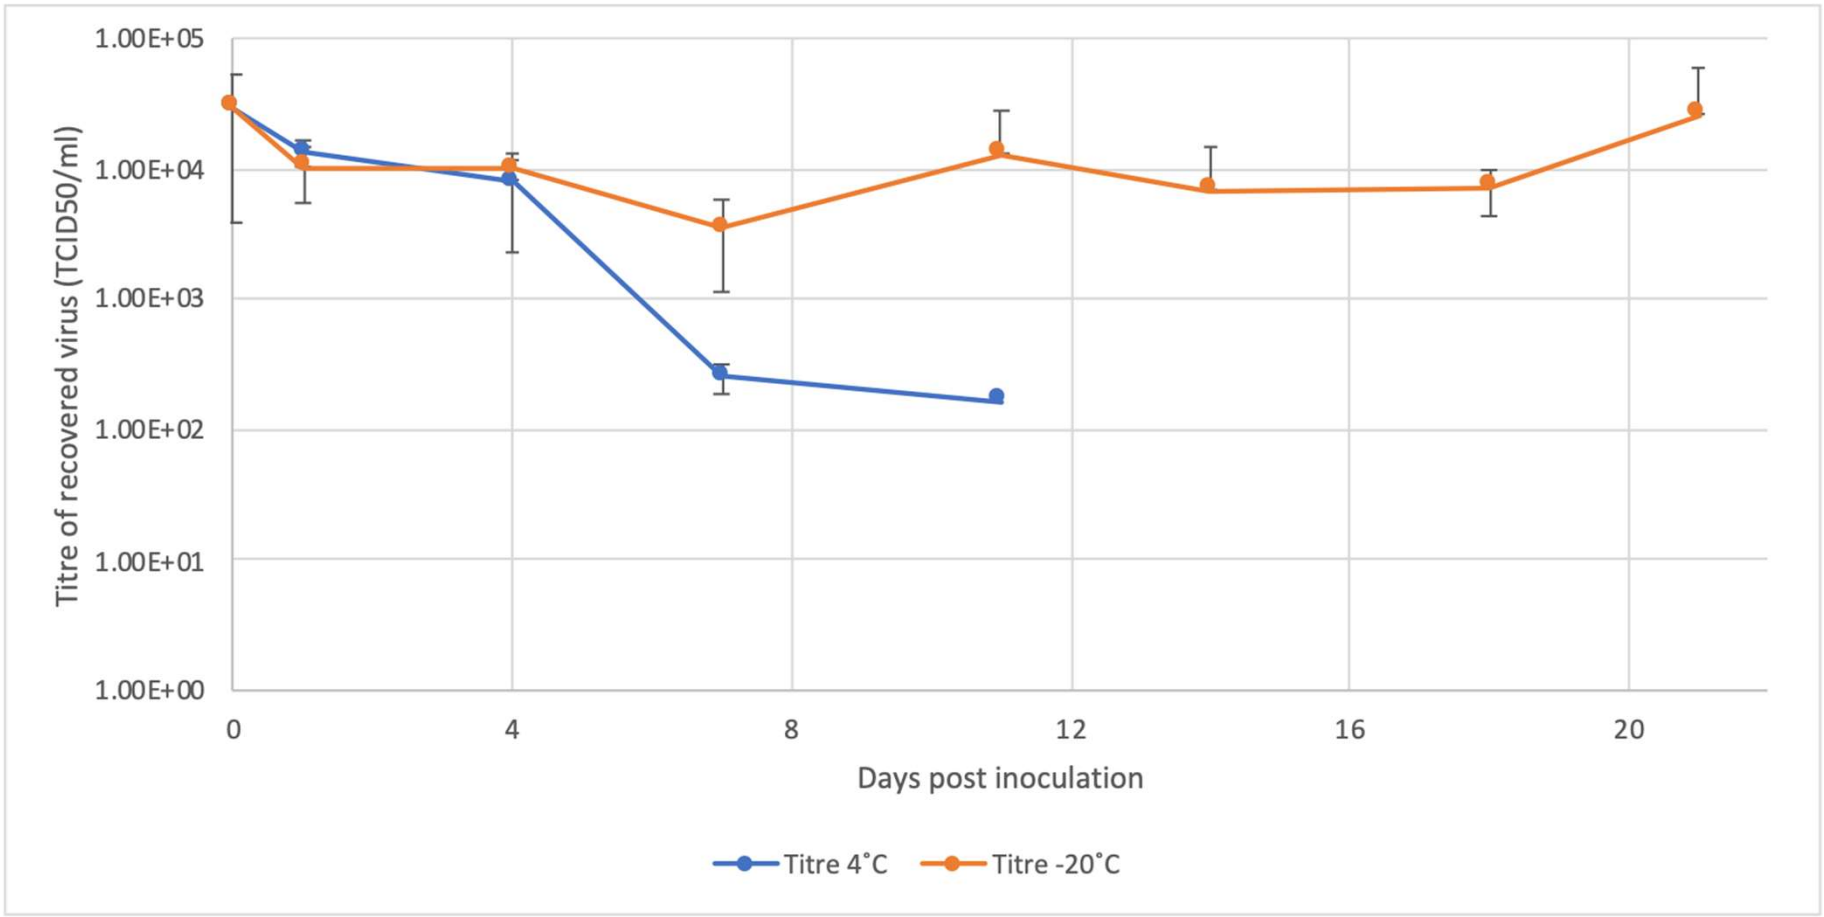
4 pools resulted very close to the limit of detection

Single samples repeated (40)

& Repeated the extraction from original samples

(31 swabs and 9 fresh vegetables)

All the samples resulted negative



Russell, 2021

Is there a risk from food or packaging?

Guidance from the World Health Organization (WHO) for businesses also states it is highly unlikely that people can contract COVID-19 from food or food packaging.

The risk of getting sick with COVID-19 from eating or handling food, including frozen food and produce and food packages, **is considered very low.** It is possible a person can get it by touching a surface or object, including food or packaging, that has the virus on it and then touching their mouth, nose, or possibly eyes, according to the Centers for Disease Control and Prevention.

Sampling plan: the model

Time for the sampling 3 weeks - 21st January - 11th February

Cold-chain food contamination as the possible origin of COVID-19 resurgence in Beijing

Xinghuo Pang[1,2,†], Lili Ren[3,4,†], Shuangsheng Wu[1,2,†], Wentai Ma[5,6,†], Jian Yang[7], Lin Di[8], Jie Li[9], Yan Xiao[3,4], Lu Kang[5,6], Shichang Du[1,2], Jing Du[1,2], Jing Wang[1,2], Gang Li[1,2], Shuguang Zhai[1,2], Lijuan Chen[1,2], Wenxiong Zhou[8], Shengjie Lai[10], Lei Gao[7], Yang Pan[1,2,*], Quanyi Wang[1,2,*], Mingkun Li[5,6,11,*], Jianbin Wang[9,12,13,*], Yanyi Huang[8,14,*], Jianwei Wang[3,4,*], COVID-19 Field Response Group[1,2] and COVID-19 Laboratory Testing Group[1,2]

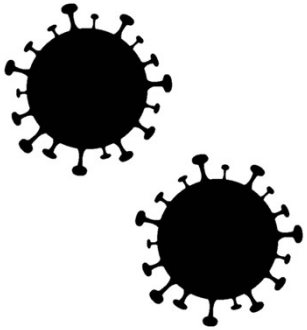
COVID-19, caused by SARS-CoV-2 [1,2], has been contained in China through stringent non-pharmaceutical interventions. Border control and quarantine have effectively prevented the virus from being spread by infected travellers, but the risk of resurgence caused by other routes of introduction and transmission remains unclear, and current strategies to prevent resurgence could be flawed. Since July, SARS-CoV-2 RNA contaminations in frozen food imported from countries with ongoing epidemics have been reported in nine provinces in China [3,4]. However, there is no robust evidence of COVID-19 outbreaks initiated by environment-to-human transmission. Here we add to evidence of such transmission by investigating the recent COVID-19 resurgence in Beijing.

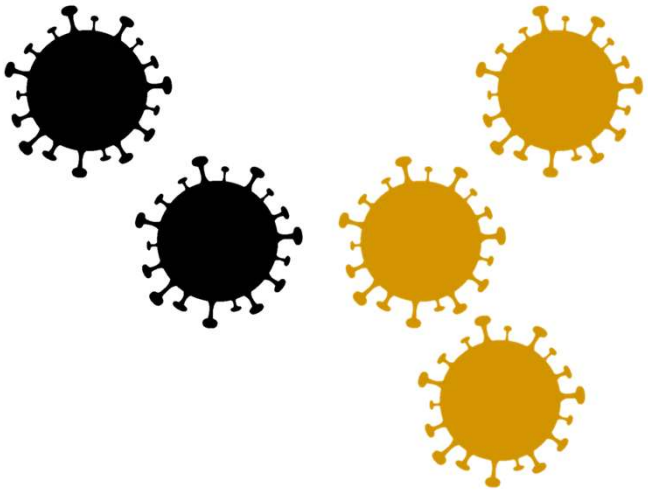
On 11 June 2020, a 52-year old man suffering from fever and cough was diagnosed with COVID-19 in Beijing, after a 56-day zero new case interval. He had no exposure history of known COVID-19 cases. On 12 June, 112 close contacts of the index case and 242 environmental samples collected from the places that he had visited were tested by quantitative reverse transcription polymerase chain reaction (qRT-PCR). All close contacts were negative, but two environmental samples from Xinfadi Market (XFDM) were positive for SARS-CoV-2. This led to in-depth investigation to confirm the role of XFDM in virus spread. A total of 538 employees from the booths that were close to the SARS-CoV-2-positive environmental samples were tested, and 45 were positive by qRT-PCR.

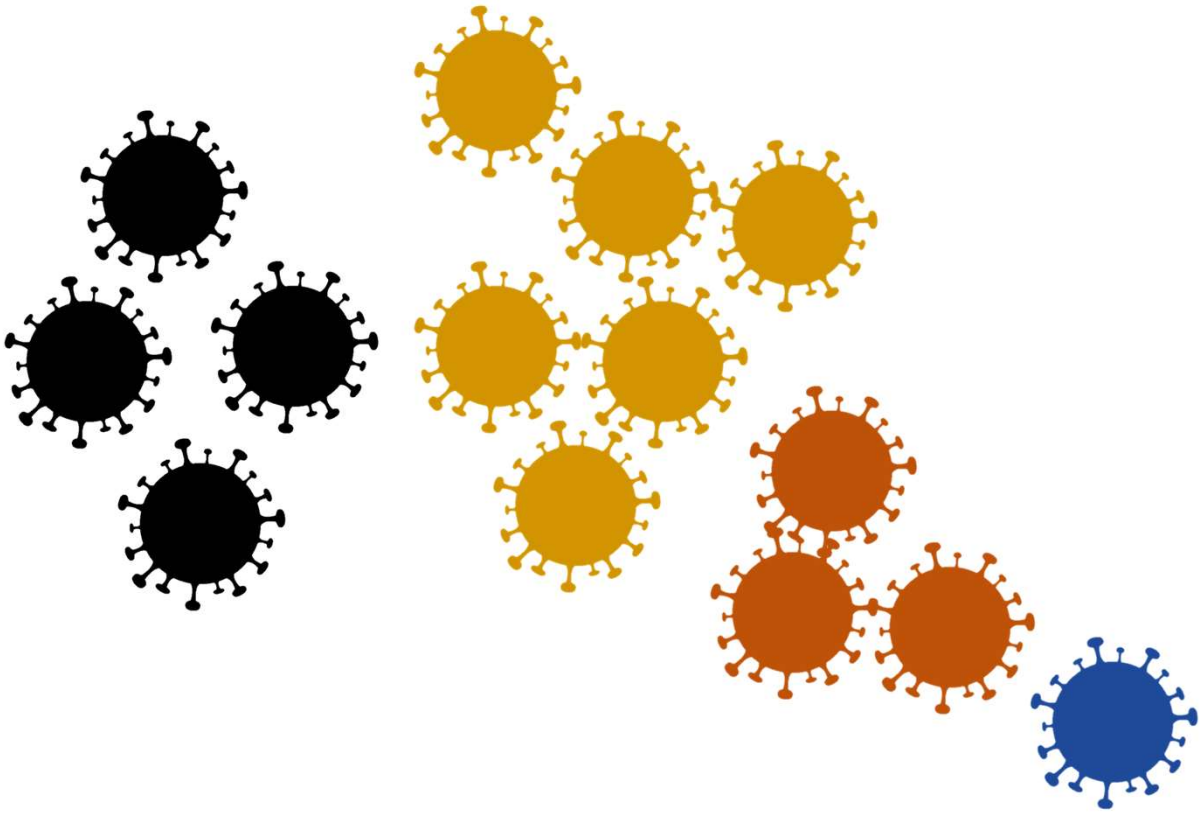
To evaluate the extent of infection spreading, a screening campaign of SARS-CoV-2 infection was implemented over the city by Beijing Center for Disease Prevention and Control. Between 15 June and 10 July, a total of more than 10 million citizens, and 5342 environmental samples were screened. Eventually 368 qRT-PCR positive cases were confirmed (Fig. S1A), of which 169 (45.9%) had a history of working in XFDM. Of the visitors to XFDM between May 30 and 12 June, 103 (28.0%) were diagnosed. The remaining 96 (26.1%) patients had contact with the infected employees or visitors. These findings suggested a single outbreak source in Beijing (Fig. S1B). Retrospective epidemiological investigation revealed the earliest symptom onset of a patient on 4 June (Fig. S1C).

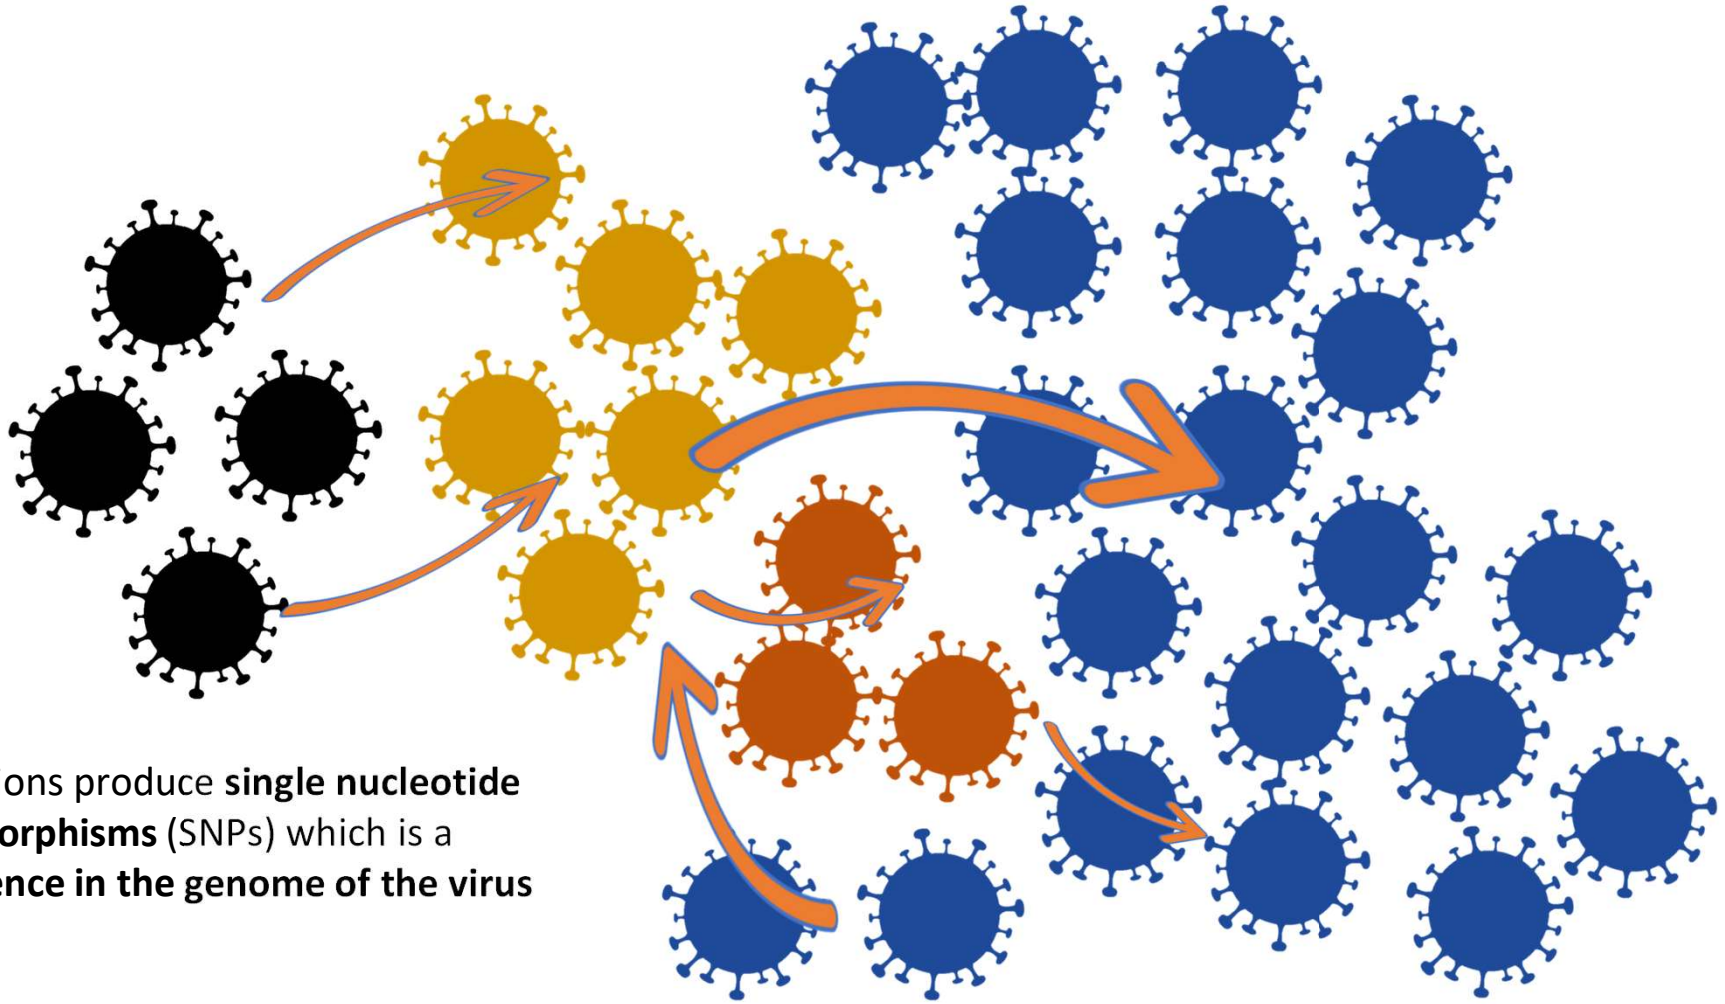
To probe the origin of the infection, we analysed the spatial distribution of infected employees in XFDM. Strikingly, 20.9% (122/584) of employees working in the basement of the XFDM trading hall (XFDM-TH) were positive for SARS-CoV-2, which is significantly higher than those of other areas in the market (1.7%, 47/2727, $\chi^2 = 363.29$, $P < 0.001$). Meanwhile, their symptom onset dates were also earlier than other employees in the market (Fig. S2). The infections demonstrated spatial clusters in the basement, and highly clustered cases were identified in the seafood section (Table S1, Figs 1A and S3).

We further identified 14 booths (Figs 1A and S4) in XFDM-TH with both employee infections and environmental contaminations, and 3294 individuals who visited these booths from 20 to 31 May. Serological screenings identified five visitors positive for IgG/IgM antibodies against SARS-CoV-2, and they had all been to the booth #S14. In contrast, no other booth was visited by more than two of these five visitors. All five visitors were negative for qRT-PCR, and none of their close contacts was infected based on qRT-PCR and antibody tests. These









Mutations produce **single nucleotide polymorphisms** (SNPs) which is a **difference in the genome of the virus**
